DT2470 Lab 02: Teh Machine Learnings

Group 6: Sergi Andreu and Carsten van de Kamp

In this lab you will practice some fundamental concepts of machine learning. In the first part you will work with an artificial dataset. The second part involves a music dataset. There's a lot more to explore, so this lab only scratches the surface!

The lab report you submit should be a testament to your intelligence, as well as a reflection of your willingness to be a part of this module. You are free to use whatever software you want, e.g., python, MATLAB, Processing, C++, etc. But I give tips below in python.

- Numpy API
- Pandas API
- Scikit-learn API
- MatPlotlib API
- Numpy Cheat Sheet
- Pydub API

I also include some images so you can confirm whether you are on the right track, or just to have a brief pause to laugh at how far your answer is from being correct.

Names: Sergi Andreu and Carsten van de Kamp

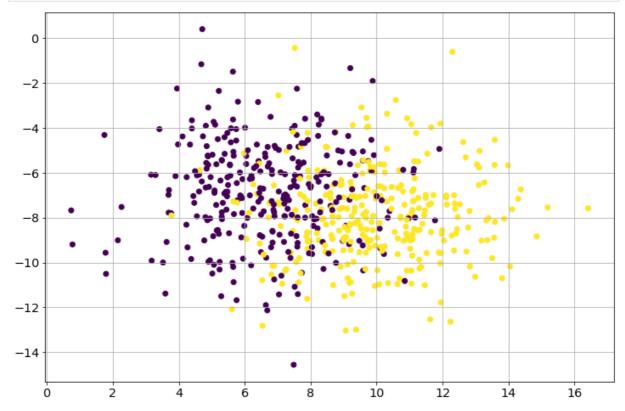

Part 1: Basics

In this part, you will explore some basic principles of machine learning. First we are going to synthesize a "toy" dataset, where we know everything about the data. This is the "best case scenario", and can help us understand ML methods and their parameters, as well as debug implementations.

For more information:

sklearn.datasets

```
# make a scatter plot of the dataset
fig, ax = plt.subplots()
plt.scatter(X[:,0],X[:,1],c=y)
plt.grid(); plt.show()
```

Create a 80/20 train/test split of your data. See sklearn.model_selection for the function train_test_split.

1.2

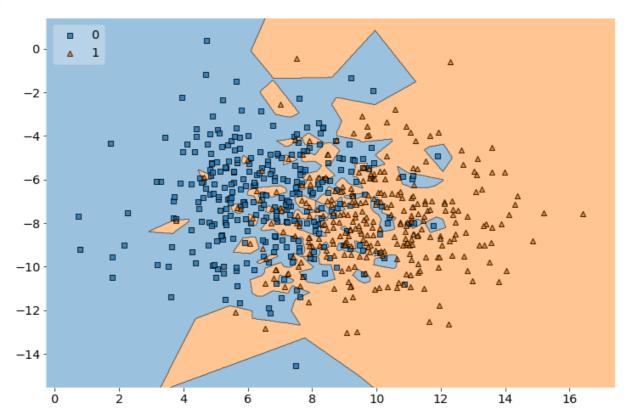

Create an instance of a nearest neighbor classifier and train it with your *training* data. See sklearn.neighbors for the appropriate function.

```
# add your code below
from sklearn.neighbors import KNeighborsClassifier
neigh1 = KNeighborsClassifier(n_neighbors=1)
neigh1.fit(X_train, y_train)
```

Out[3]: KNeighborsClassifier(n_neighbors=1)

Plot the decision boundary of your trained classifier. Use the *plot_decision_regions* function in mlxtend.plotting.

Out[4]: <AxesSubplot:>

1.4

Use your classifier to label the hold out set, and print out the predicted labels and true labels.

Print the confusion matrix of the results. See sklearn.metrics for a relevant function.

```
In [6]:
         # add your code below
         from sklearn.metrics import confusion_matrix, ConfusionMatrixDisplay
          conf_matrix = confusion_matrix(y_test, y_pred)
          print(conf_matrix)
          disp = ConfusionMatrixDisplay(conf_matrix, display_labels=['0', '1'])
         disp.plot()
         [[51 13]
         [13 43]]
         <sklearn.metrics._plot.confusion_matrix.ConfusionMatrixDisplay at 0x218dd567490>
Out[6]:
                                                                                        - 50
                                                                                        - 45
            0
                             51
                                                              13
                                                                                        - 40
                                                                                        - 35
         True label
                                                                                        - 30
                                                                                        -25
                             13
                                                              43
            1
                                                                                        -20
```

1.6

0

Use the *classification_report* function of sklearn.metrics to print out more metrics for your classifier.

Predicted label

1

```
from sklearn.metrics import classification_report
# add your code below

target_names = ['class 0', 'class 1']
print(classification_report(y_test, y_pred, target_names=target_names))

precision recall f1-score support

class 0 0.80 0.80 0.80 64
```

class 1	0.77	0.77	0.77	56
accuracy			0.78	120
macro avg	0.78	0.78	0.78	120
weighted avg	0.78	0.78	0.78	120

Now you will explore k nearest neighbor classification with the toy dataset. Create a 50/30/20 train/validation/test split of your data.

```
In [8]: # add your code below

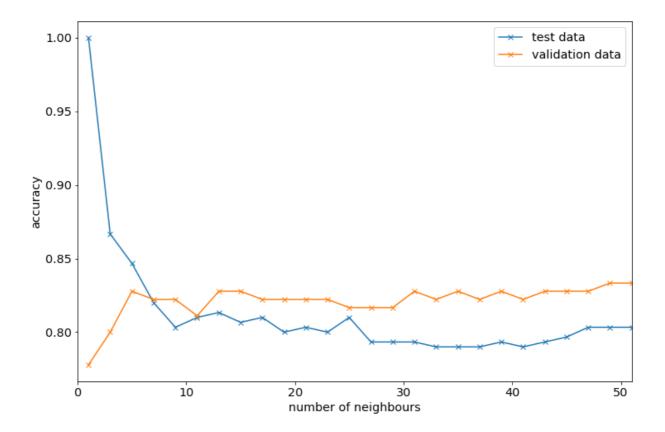

X_train2, X_test2, y_train2, y_test2 = train_test_split(X, y, test_size=0.2)

X_train2, X_val2, y_train2, y_val2 = train_test_split(X_train2, y_train2, test_size=
```

1.8

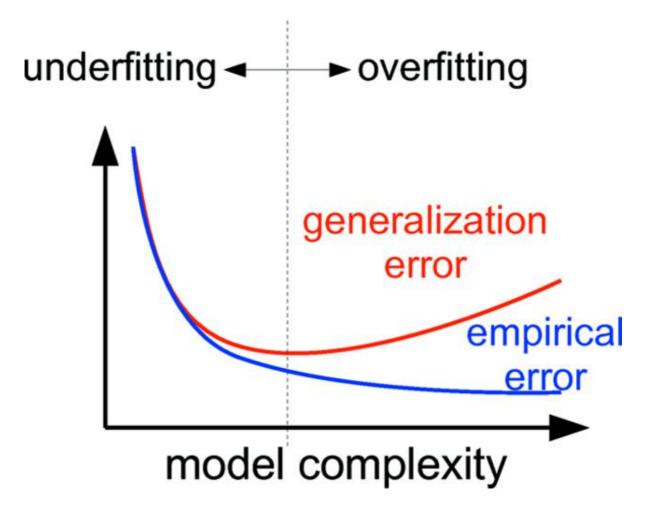

For k in 1 to 51 by odd integers, train a kNN classifier and compute its accuracy on the training dataset and the validation dataset. Plot these accuracies as a function of k.

```
In [9]:
          # add your code below
          ks = [(2*i + 1) \text{ for } i \text{ in } range(26)]
          test_acc = []
          val_acc = []
          for k in ks:
               neigh2 = KNeighborsClassifier(n_neighbors=k)
               neigh2.fit(X_train2, y_train2)
               test_acc.append(neigh2.score(X_train2, y_train2))
               val_acc.append(neigh2.score(X_val2, y_val2))
          # Plotting
          fig, ax = plt.subplots()
          ax.plot(ks, test_acc, 'x-', label='test data')
ax.plot(ks, val_acc, 'x-', label='validation data')
          ax.set_xlim((0,51))
          # ax.set_ylim((0.7,1))
          ax.set_xlabel('number of neighbours')
          ax.set_ylabel('accuracy')
          ax.legend()
          plt.show()
```

Generalization, Overfitting, and Underfitting

- If a model is able to make accurate predictions on unseen data:
 - it is able to **generalize** from the training set to the test set.
- Building a model that is too complex for the amount of information in the data is called overfitting.
- This refers to the complexity of the decision boundary, **NOT** computational complexity.

The complexity of KNN models decreases with K. Find the K with the highest validation accuracy, and train a kNN classifier with that K on the training data. Test it on the testing data and print its classification_report. If there are several possible K, choose one by some strategy.

```
In [10]:
# Determine the best k, which is found where the validation accuracy is maximal.
# If there are several possible k, we choose the largest value because we favour a s
# Small k yields a complex decision boundary, using a small k is prone to overfittin
best_k = np.max(ks[np.argmax(val_acc)])

neigh_best_k = KNeighborsClassifier(n_neighbors=best_k)
neigh_best_k.fit(X_train2, y_train2)

y_pred2 = neigh_best_k.predict(X_test2)
print(f'The best k is {best_k}. \n')
print(classification_report(y_test2, y_pred2, target_names=target_names))
```

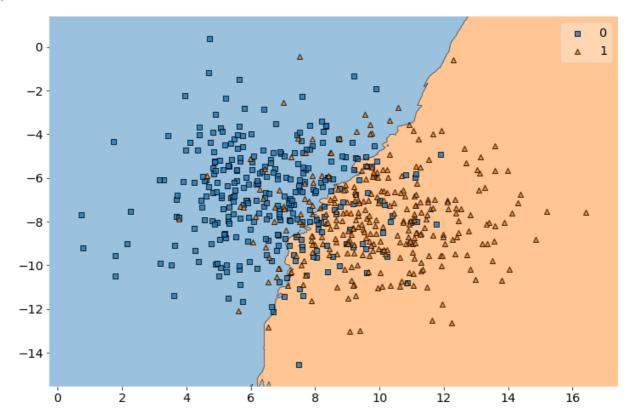

The best k is 49.

	precision	recall	f1-score	support
class 0 class 1	0.83 0.79	0.81 0.80	0.82 0.80	64 56
accuracy macro avg weighted avg	0.81 0.81	0.81 0.81	0.81 0.81 0.81	120 120 120

For this classifier, plot its decision boundary, and compare with the boundary you see in #1.3.

```
In [11]: plot_decision_regions(X, y, clf=neigh_best_k)
```

Out[11]: <AxesSubplot:>

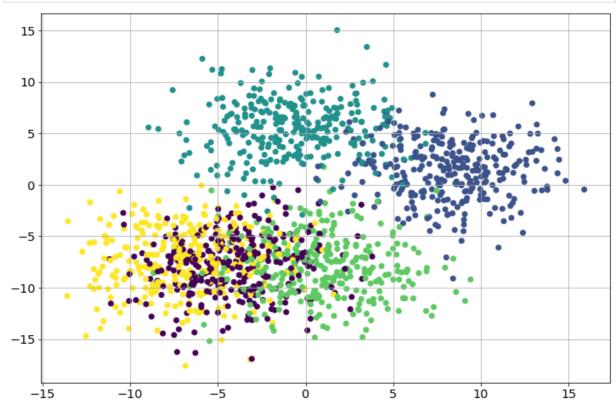

Compared to the decision boundary in assignment 1.3 we see that this one is much smoother. Therefore we can assume that it generalizes better on unseen data. The non-smoothness in the decision boundary is caused by specific properties in the training data that are unlikely to be found in new unseen data.

1.11

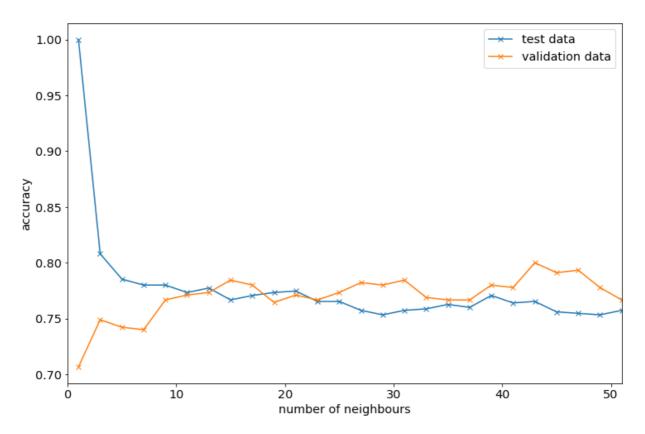

Change the toy dataset (number of classes, number of observations, cluster spread) and repeat the above. What happens as the cluster spread increase? What happens if there are more classes?

```
# make a scatter plot of the dataset
fig, ax = plt.subplots()
plt.scatter(X3[:,0],X3[:,1],c=y3)
plt.grid(); plt.show()
```

```
In [13]: # Split the data in a 50/30/20 train/validation/test set
    X_train3, X_test3, y_train3, y_test3 = train_test_split(X3, y3, test_size=0.2)
    X_train3, X_val3, y_train3, y_val3 = train_test_split(X_train3, y_train3, test_size=
```

```
In [14]:
          # add your code below
          ks = [(2*i + 1) \text{ for } i \text{ in } range(26)]
          test_acc3 = []
          val_acc3 = []
          for k in ks:
               neigh3 = KNeighborsClassifier(n_neighbors=k)
               neigh3.fit(X_train3, y_train3)
               test_acc3.append(neigh3.score(X_train3, y_train3))
               val_acc3.append(neigh3.score(X_val3, y_val3))
          fig, ax = plt.subplots()
          ax.plot(ks, test_acc3, 'x-', label='test data')
          ax.plot(ks, val_acc3, 'x-', label='validation data')
          ax.set_xlim((0,51))
          # ax.set_ylim((0.9,1))
          ax.set_xlabel('number of neighbours')
          ax.set_ylabel('accuracy')
          ax.legend()
```

```
In [15]:
# Determine the best k, which is found where the validation accuracy is maximal.
# If there are several possible k, we choose the largest value because we favour a s
# Small k yields a complex decision boundary, using a small k is prone to overfittin
best_k3 = np.max(ks[np.argmax(val_acc3)])

neigh_best_k3 = KNeighborsClassifier(n_neighbors=best_k3)
neigh_best_k3.fit(X_train3, y_train3)

y_pred3 = neigh_best_k3.predict(X_test3)

target_names3 = [f'class {c}' for c in np.arange(0,numClasses3)]
print(f'The best k is {best_k3}. \n')
print(classification_report(y_test3, y_pred3, target_names=target_names3))
```

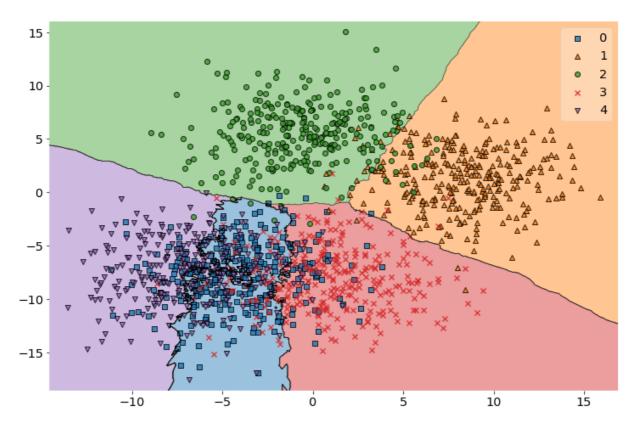

The best k is 43.

```

C:\Users\sergi\Anaconda3\lib\site-packages\mlxtend\plotting\decision_regions.py:274: UserWarning: You passed a edgecolor/edgecolors ('black') for an unfilled marker ('x'). Matplotlib is ignoring the edgecolor in favor of the facecolor. This behavi or may change in the future.

```
ax.scatter(x=x_data,
```

When the cluster spread increases, then the data sets are more likely to overlap and hence the confusion increases. It is harder for the classifier do determine a good decision boundary (because a hard decision boundary might not exist) and the accuracy is lower. We notice that the optimal \$k\$ is in general higher compared to the case where there is little overlap.

When there are more classes, then again the probability of overlap between the data cloud from different classes increases, again resulting in less accuracy and a higher optimal \$k\$.

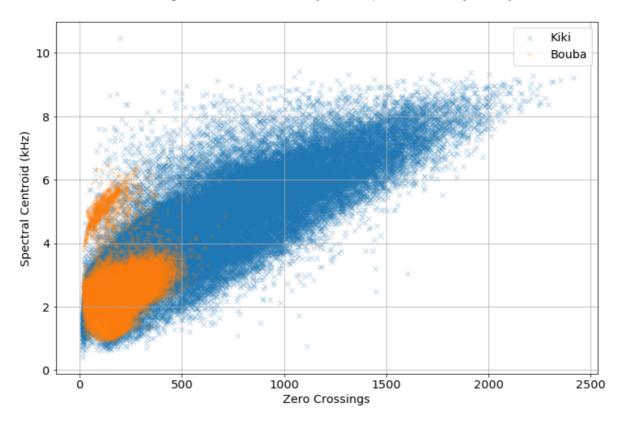

Part 2: Application

In this portion of the lab, you will work with audio recordings of two music genres: *Kiki* and *Bouba*. These genres are popular amongst the beings that inhabit the digital world. Download the zipfile from the Canvas lab 02 page, unzip, and put them somewhere you can find them.

Below are two functions we will use to extract features from the audio data.

```
In [17]:
          def extractZC( data, windowsizeinsamples, windowhopinsamples ):
              totalnumberofwindows = np.floor((len(data)-windowsizeinsamples)/windowhopinsampl
              numbersignchanges = []
              for ii in np.arange(totalnumberofwindows):
                  windowstart = np.int(ii*windowhopinsamples)
                  windowend = np.int(windowstart + windowhopinsamples)
                  datasign = np.sign(data[windowstart:windowend])
                  datasignderivative = datasign - np.roll(datasign,1)
                  numbersignchanges.append(np.count_nonzero(datasignderivative[1:-1]))
              return np.array(numbersignchanges)
          def extractSC( data, windowsizeinsamples, windowhopinsamples, samplerate ):
              totalnumberofwindows = np.floor((len(data)-windowsizeinsamples)/windowhopinsampl
              centroid = []
              freqs = np.arange(np.ceil(windowsizeinsamples/2.0)+1)*samplerate/windowsizeinsam
              for ii in np.arange(totalnumberofwindows):
                  windowstart = np.int(ii*windowhopinsamples)
                  windowend = np.int(windowstart + windowsizeinsamples)
```

Using the functions above, compute zero crossing and spectral centroid features for all kiki and bouba training data files using contiguous 100 ms frames. (Ignore any frames at the end of audio files that are less than that length.) Create a two-dimensional scatter plot of the features extracted from the training data. Below is what my scatter plot looks like, just so you know.

```
In [18]:
          import sys
          import os
          sys.path.append(os.getcwd())
          def extract_features(path, frame_size_seconds, window_hop_seconds):
              ZC_array = np.array([])
              SC_array = np.array([])
              for file in os.scandir(path):
                  if file.path.endswith(".m4a"):
                      print("analyzing ", file.name, file.path)
                      sound = pydub.AudioSegment.from_file(path + "/" + file.name, format = "m"
                      sample_rate = sound.frame_rate
                      windowsizeinsamples = frame_size_seconds * sample_rate
                      windowhopinsamples = window_hop_seconds * sample_rate
                      samples = sound.get_array_of_samples()
                      ZC = extractZC( samples, windowsizeinsamples, windowhopinsamples )
                      SC = extractSC( samples, windowsizeinsamples, windowhopinsamples, sample
```

```
ZC_array = np.append(ZC_array, ZC)
SC_array = np.append(SC_array, SC)
return ZC_array, SC_array
```

In [19]:

```
# add your code below
import pydub
import os

kiki_train_path = 'KikiBoubadata/kikibouba_train/kiki'
bouba_train_path = 'KikiBoubadata/kikibouba_train/bouba'

ax4.set_ylabel('Density')
ax4.yaxis.set_label_position("right")
plt.figtext(0.51, 1, "Kiki", ha='center', va='center', fontsize=20)
plt.figtext(0.51, 0.5, "Bouba", ha='center', va='center', fontsize=20)
fig.tight_layout()
plt.subplots_adjust(hspace=.3) # some extra space for the subtitles
plt.show()
```

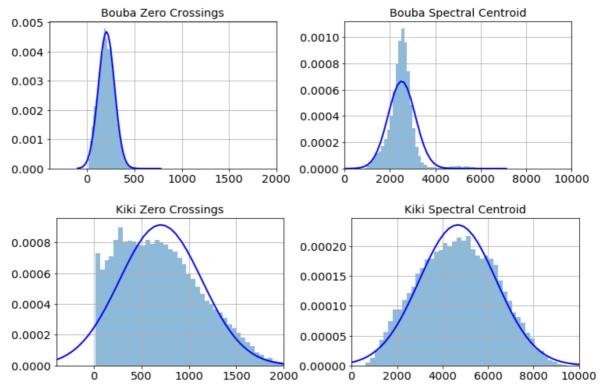

Let's model *each* feature of the *each* class by a Gaussian distribution. This means we want to approximate each histogram of each feature observed in class g by a Gaussian function with mean $\mu_{*,g}$ and variance $\sum_{x,g}^2 \frac{x}{G}(x|g) = \frac{1}{\sqrt{2\pi}} \frac{x}{g}^2} \left[-(x-\mu_{*,g})^2/2 \right]$

Use unbiased maximum likelihood estimation (MLE) to compute the parameters of the two distributions using your training observations. Remember, the MLE mean of \$N\$ numbers $\{x_1, x_2, \ldots, x_n\}$ is given by $\{x_1, x_2, \ldots, x_n\}$ and the MLE variance is given by $\{x_1, x_2, \ldots, x_n\}$ and the MLE variance is given by $\{x_1, x_2, \ldots, x_n\}$

Plot these four distributions, overlayed on the normalized histograms of the features for the two classes.

Here's what mine look like:

```
from scipy.stats import norm

# add your code below
kiki_train_ZC_mu = np.sum(kiki_train_ZC) / len(kiki_train_ZC)
kiki_train_ZC_var = np.sum( (kiki_train_ZC - kiki_train_ZC_mu)**2 ) / (len(kiki_train_kiki_train_ZC_gaussfit = lambda x: norm.pdf(x, kiki_train_ZC_mu, kiki_train_ZC_var**
kiki_train_SC_mu = np.sum(kiki_train_SC) / len(kiki_train_SC)
kiki_train_SC_var = np.sum( (kiki_train_SC - kiki_train_SC_mu)**2 ) / (len(kiki_train_kiki_train_SC_gaussfit = lambda x: norm.pdf(x, kiki_train_SC_mu, kiki_train_SC_var**

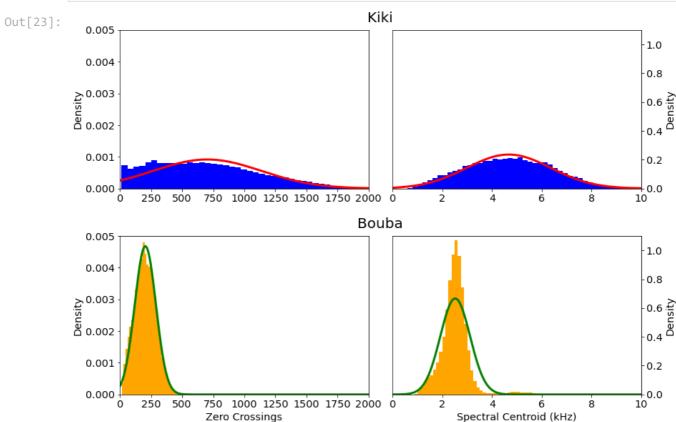

bouba_train_ZC_mu = np.sum(bouba_train_ZC) / len(bouba_train_ZC)
bouba_train_ZC_var = np.sum( (bouba_train_ZC - bouba_train_ZC_mu)**2 ) / (len(bouba_bouba_train_ZC_gaussfit = lambda x: norm.pdf(x, bouba_train_SC)
bouba_train_SC_mu = np.sum(bouba_train_SC) / len(bouba_train_SC)
bouba_train_SC_var = np.sum( (bouba_train_SC - bouba_train_SC_mu)**2 ) / (len(bouba_bouba_train_SC_gaussfit = lambda x: norm.pdf(x, bouba_train_SC_mu) + 2 ) / (len(bouba_bouba_train_SC_gaussfit = lambda x: norm.pdf(x, bouba_train_SC_mu) + 2 ) / (len(bouba_bouba_train_SC_gaussfit = lambda x: norm.pdf(x, bouba_train_SC_mu) + 2 ) / (len(bouba_bouba_train_SC_gaussfit = lambda x: norm.pdf(x, bouba_train_SC_mu) + 2 ) / (len(bouba_bouba_train_SC_gaussfit = lambda x: norm.pdf(x, bouba_train_SC_mu) + 2 ) / (len(bouba_bouba_train_SC_gaussfit = lambda x: norm.pdf(x, bouba_train_SC_mu) + 2 ) / (len(bouba_bouba_train_SC_mu) + 2 ) / (len(bouba_train_SC_mu) + 2 ) /
```

```
x_ZC = np.linspace(0,2500,num=1000)
x_SC = np.linspace(0,10, num=1000)

ax1.plot(x_ZC, kiki_train_ZC_gaussfit(x_ZC), 'r-', linewidth=3)
ax2.plot(x_SC, kiki_train_SC_gaussfit(x_SC), 'r-', linewidth=3)

ax4.plot(x_SC, bouba_train_SC_gaussfit(x_SC), 'g-', linewidth=3)

fig
```

Given a particular two-dimensional observation \$\mathbf{x}\$ extracted from an audio file, we want to estimate the probaility of \$\mathbf{x}\$ coming from class \$g \in \{\textrm{Kiki},\textrm{Bouba}\}\$, i.e., the *posterior* \$P[g|\mathbf{x}]\$. By Bayes' Theorem, we can express this probability as:

 $p[G=g]\mathbb{X} = \frac{f_{\mathrm{X}}[G](\mathbb{X})[G=g)P[G=g]}{f_\mathrm{X}}(\mathbb{X})$

where the *likelihood* $f_{\mathrm{X}|G}(\mathbb{x}|G=g)$ is the probability density of observing $\mathrm{F}_{x}\$ from class g, P[G=g] is the *prior* probability of encountering g regardless of what we observe, and $f_{\mathrm{X}(\mathbb{x})}$ is the probability density of observing $\mathrm{F}_{x}\$ no matter what class.

We define the *posterior odds* of Kiki as the ratio: $\$O(G=\text{Kiki}|\mathbb{x}) = \frac{P[G=\text{Kiki}|\mathbb{x}]}{P[G=\text{Bouba}|\mathbb{x}]}$ \$ Similarly, the posterior odds of Bouba is the ratio $\$O(G=\text{Bouba}|\mathbb{x}) =$

These are easy to understand. For instance, if O(G=Kiki) = 2, then according to our model Kiki is twice as likely given \mathbb{F}_{x} than Bouba, or Bouba is half as likely as Kiki. By plugging in the equation for $P[G=g]\mathbb{F}_x$, the odds of Kiki can be expressed

 $$$O(G=\text{Kiki}|\mathbb{X}) = \frac{f_{\mathrm{Kiki}}|G_{\mathrm{Kiki}}} \\ {f_{\mathrm{Kiki}}|G_{\mathrm{Kiki}}} \\ {f_{\mathrm$

If for an observation $O(G=\text{Kiki}|\mathbb{X}) > 2$, then we might label it as Kiki. Otherwise we could label it Bouba. We just need to compute the densities $f_{\mathbb{X}}G$ (\mathbf{x}|G=g)\$.

This is where our Gaussian models come into play. We know the first element of \$\mathbf{x}\\$ is the zero crossing feature, and the second element is spectral centroid. If we assume these two features are independent, then:

 $f_{X}[G](x_z,x_s|G=g) = f_{X_z}G(x_z|G=g)f_{X_s}G(x_s|G=g)$ where x_z is the zero crossing feature, and x_s is the spectral centroid features. If we assume each feature is distributed Gaussian, then

Given our estimates of these four parameters \$\

 ${\mu_{z,g},\sigma_{z,g}^2,\$ for Kiki and for Bouba, we are *almost* ready to build a classification system.

We need to estimate the prior probabilities, P[G=Kiki] and P[G=Bouba].

To do that, assume the training data reflects how observations are distributed in the real world, and estimate P[G=Kiki] as the proportion of observations of Kiki in the training dataset, and P[G=Bouba] as the proportion of observations of Bouba in the training dataset.

```
In [24]: # add your code below

kiki_train_prior = len(kiki_train_ZC) / (len(kiki_train_ZC) + len(bouba_train_ZC))
bouba_train_prior = len(bouba_train_ZC) / (len(kiki_train_ZC) + len(bouba_train_ZC))
assert kiki_train_prior + bouba_train_prior == 1
```

2.5

Now write a function using all the parameters you have estimated that computes the posterior odds of Kiki given a two-dimensional observation, and returns 1 (Kiki) if the odds are greater than 2, and otherwise 0 (Bouba). Use the MLE parameters you found in the previous part.

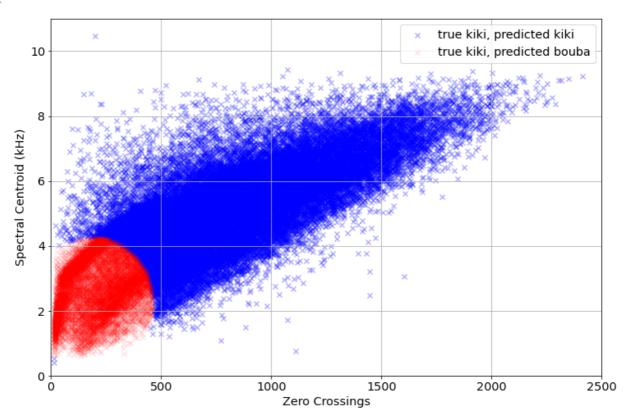

```
# add your code below
def kiki_posterior_odds_greater2(x,
                                 kiki_train_prior = kiki_train_prior,
                                 bouba train prior = bouba train prior,
                                 kiki_train_ZC_gaussfit = kiki_train_ZC_gaussfit,
                                 kiki_train_SC_gaussfit = kiki_train_SC_gaussfit,
                                 bouba_train_ZC_gaussfit = bouba_train_ZC_gaussfit,
                                 bouba_train_SC_gaussfit = bouba_train_SC_gaussfit):
    Compute posterior odds of kiki given a 2D observation x = [num_zero_crossings, s
    if odds > 2, returns 1 (=Kiki)
    else returns 0 (=Bouba)
    prior_ratio = kiki_train_prior / bouba_train_prior
   ZC = x[0]
   SC = x[1]
    kiki_likelihood = kiki_train_ZC_gaussfit(ZC) * kiki_train_SC_gaussfit(SC)
    bouba_likelihood = bouba_train_ZC_gaussfit(ZC) * bouba_train_SC_gaussfit(SC)
    kiki_posterior_odds = kiki_likelihood / bouba_likelihood * prior_ratio
    return True if (kiki_posterior_odds > 2) else False
```

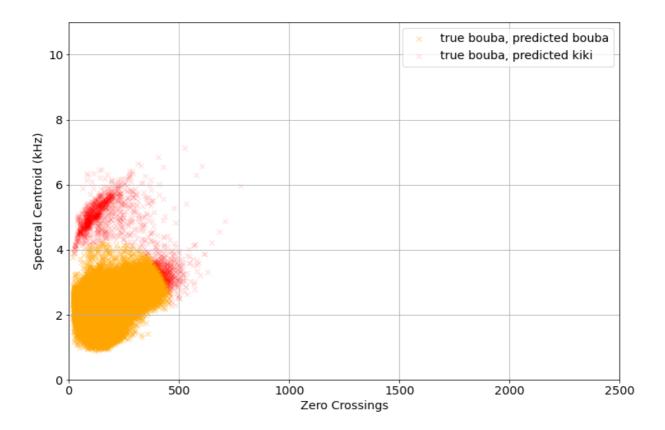

Use your function to label all observations in the training data and create one scatter plot of the labeled Kiki observations, and one scatter plot of the labeled Bouba observations, both colorcoded by the predicted labels. (This should take some time to compute because the classifier you have created is not very optimized.)

```
In [26]:
         # add your code below
         kiki_training_data = np.stack((kiki_train_ZC, kiki_train_SC), axis=1)
         bouba training data = np.stack((bouba train ZC, bouba train SC), axis=1)
         training_data = np.concatenate((kiki_training_data, bouba_training_data))
In [27]:
         # Predicting labels using classifier
         kiki_true_labels = np.ones( len(kiki_train_ZC), dtype=bool)
         bouba_true_labels = np.zeros(len(bouba_train_ZC), dtype=bool)
         true_labels = np.concatenate((kiki_true_labels, bouba_true_labels))
         kiki_predicted_labels = np.array([kiki_posterior_odds_greater2(sample) for sample
         predicted labels = np.concatenate((kiki predicted labels, bouba predicted labels))
In [28]:
         # Plotting
         fig1, ax1 = plt.subplots()
         ax1.scatter(kiki_training_data[kiki_predicted_labels, 0],
                    kiki training data[kiki predicted labels, 1],
                    c='blue', marker='x', alpha=0.3, label='true kiki, predicted kiki')
         ax1.scatter(kiki_training_data[~kiki_predicted_labels, 0],
                    kiki_training_data[~kiki_predicted_labels, 1],
```

```
c='red', marker='x', alpha=0.1, label='true kiki, predicted bouba')
ax1.legend()
ax1.set xlabel('Zero Crossings')
ax1.set_ylabel('Spectral Centroid (kHz)')
ax1.grid()
ax1.set_xlim((0,2500))
ax1.set_ylim((0,11))
fig2, ax2 = plt.subplots()
ax2.scatter(bouba_training_data[~bouba_predicted_labels, 0],
            bouba_training_data[~bouba_predicted_labels, 1],
            c='orange', marker='x', alpha=0.3, label='true bouba, predicted bouba')
ax2.scatter(bouba_training_data[bouba_predicted_labels, 0],
            bouba_training_data[bouba_predicted_labels, 1],

ax2.legend()
ax2.set_xlabel('Zero Crossings')
ax2.set_ylabel('Spectral Centroid (kHz)')
ax2.grid()
ax2.set_xlim((0,2500))
ax2.set_ylim((0,11))
```

Out[28]: (0.0, 11.0)

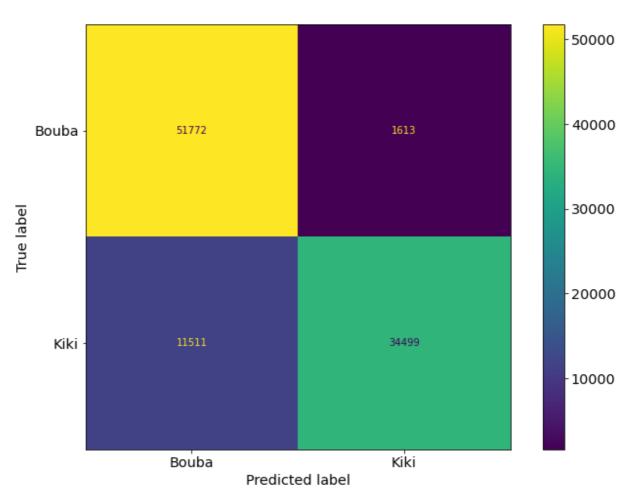

Explain what you see, and how it compares to the scatter plot you created in #2.1.

The classifier came up with a clear and hard decision boundary to predict whether a sample belongs to either the Kiki class or the Bouba class. In the scatter plot in 2.1 (true labels) we see that there are some Kikia samples that have the same properties as typical Kiki samples. Our classifier cannot deal with these.

2.8

Compute a confusion table summarizing the results of your classifier on the training dataset.

Compute the accuracy and balanced accuracy. Compute the precision and recall for both classes.

bouba_0171.m4a KikiBoubadata/kikibouba_test/bouba\bouba_0171.m4a

analyzing

TEST DATA Accuracy: 0.87,

Balanced accuracy: 0.86,

Precision: 0.95, Recall: 0.74

Again, we see that the classifier performs very well in classifying true Bouba samples as Bouba, with few true Bouba sample classified as Kiki. On the other hand, it classifies true Kiki samples more often as Bouba samples due to the hard decision boundary and overlap between the features.

We see that all performance metrics (confusion matrix, accuracy, balanced accuracy, precision, recall) on the test data are very comparable to the values we saw on the training data, which is a good sign and shows that we are not overfitting to the training data.

2.10

Discuss several ways you might build a better Kiki-Bouba classifier.

This classifier has two main drawbacks. Most important is that there is no clear decision boundary in the feature space (zero crossings x spectral centroid), making it impossible to have a perfect classifier from the beginning. One could investigate if this issue could be resolved by choosing more and/or different features that can be extracted from the audio samples. This way we might find a certain feature space in which we can draw a clearer and better decicion boundary between the Kiki and Bouba samples. This would especially reduce the number of true Kiki samples that are classified as belonging to the Bouba class.

One could also check what influence the chosen frame size and hop size have on the classification performance. Perhaps different values would yield a better classifier.

Secondly, the implementation of the classifier can be improved, such that it is faster in predicting which class a sample belongs to. We expect that getting rid of the for-loop that runs over all samples in the classifier call would yield a big improvement in speed already. Also, one could try to find a way to reduce the number of function calls.

A bigger frame size would allow for a more efficient classification, since the frequency resolution would be better. It is also possible that some parts of the audio are silence or it is not possible to distinguish them as being from kiki or bouba. This is resolved by using a bigger frame size.

However, a big frame size would impose a mininum length for the input data. That is, if we use a frame size of 10s, we would only be able to classify between the data if we have an input of at least 10s. This may reduce the number of data, and also make the model less scalable for real-life problems.

We try using a frame size of 10s and a window size of 5s

```
In [36]: frame_size_seconds = 10.0
    window_hop_seconds = 5.0

# Kiki
    kiki_train_ZC, kiki_train_SC = extract_features(kiki_train_path, frame_size_seconds,

# Bouba
    bouba_train_ZC, bouba_train_SC = extract_features(bouba_train_path, frame_size_secon)

# Converting Hz to kHz
    kiki_train_SC = kiki_train_SC/1000
    bouba_train_SC = bouba_train_SC/1000
```

Plotting
fig, ax = plt.subplots()
ax.scatter(kiki_train_ZC,
```

```
In [37]:
                                     kiki_train_SC, c='blue', marker='x', alpha=0.3, label='ki
          ax.scatter(bouba_train_ZC, bouba_train_SC, c='orange', marker ='+', alpha=0.3, label
          ax.legend()
          ax.set_xlabel('Zero Crossings')
          ax.set_ylabel('Spectral Centroid (kHz)')
          ax.grid()
```

We can see that now the data is separable. However, in the tradeoff we have risked being able to not use all data, and to only be able to classify samples of at least 10s.

Also, more features could be introduced so as to achieve a better classification. It is however not easy to do feature engineering, specially without having taken a look into the data. One could start by plotting two signals (one from Kiki and one from Bouba) and compare them visually.

```
In [38]:
          bouba_test_path = 'KikiBoubadata/kikibouba_test/bouba'
          kiki_test_path = 'KikiBoubadata/kikibouba_test/kiki'

[<matplotlib.lines.Line2D at 0x218dfbb7580>]

Out[38]:

The spectral centroid seems a good feature for this case. However, it also seems that the variance of the frequencies may play an important role in the classification, since the frequencies of Kiki seem to be more spread (and variance is a measure of how spread it's a signal). We therefore want to extract the Spectral Variance.

```
def extractSV( data, windowsizeinsamples, windowhopinsamples, samplerate ):
    totalnumberofwindows = np.floor((len(data)-windowsizeinsamples)/windowhopinsampl
    variance = []
    freqs = np.arange(np.ceil(windowsizeinsamples/2.0)+1)*samplerate/windowsizeinsam
    #freqs = np.power(freqs, trypower)

for ii in np.arange(totalnumberofwindows):
    windowstart = np.int(ii*windowhopinsamples)
    windowend = np.int(windowstart + windowsizeinsamples)
    DATA = np.abs(np.fft.fft(data[windowstart:windowend]))
```

```
.....
        centroid = np.sum(freqs*DATA[:int(np.ceil(windowsizeinsamples/2.0)+1)])/np.s
        second_moment = np.sum(np.square(freqs)*DATA[:int(np.ceil(windowsizeinsample
        variance.append( np.subtract(second moment , centroid)
        ind_max = int(np.ceil(windowsizeinsamples/2.0)+1)
        centroid = np.sum(freqs*DATA[:ind_max])/np.sum(DATA[:ind_max])
        second_moment = np.sum(np.power(freqs, 2)*DATA[:ind_max])/np.sum(DATA[:ind_m
        variance.append(second_moment - np.power(centroid,2))
    return np.array(variance)
import sys
sys.path.append(os.getcwd())
def extract_features_2(path, frame_size_seconds, window_hop_seconds):
    ZC_array = np.array([])
    SC_array = np.array([])
    SV_array = np.array([])
    for file in os.scandir(path):
        if file.path.endswith(".m4a"):
            sound = pydub.AudioSegment.from_file(path + "/" + file.name, format = "m
            sample_rate = sound.frame_rate
            windowsizeinsamples = frame_size_seconds * sample_rate
            windowhopinsamples = window_hop_seconds * sample_rate
            samples = sound.get_array_of_samples()
            ZC = extractZC( samples, windowsizeinsamples, windowhopinsamples )
            SC = extractSC( samples, windowsizeinsamples, windowhopinsamples, sample
            SV = extractSV( samples, windowsizeinsamples, windowhopinsamples, sample
            ZC_array = np.append(ZC_array, ZC)
            SC_array = np.append(SC_array, SC)
            SV_array = np.append(SV_array, SV)
    return ZC_array, SC_array, SV_array
```

A good approach would be to use those three variables. However, we only replace the Spectral Centroid with Spectral Variance, and see if we observe better results.

```
In [40]: # add your code below
import pydub
import os

kiki_train_path = 'KikiBoubadata/kikibouba_train/kiki'
bouba_train_path = 'KikiBoubadata/kikibouba_train/bouba'

frame_size_seconds = 10.0
window_hop_seconds = 5.0

# Kiki
kiki_train_ZC, kiki_train_SC, kiki_train_SV = extract_features_2(kiki_train_path, fr
```

```
# Bouba

We could find an analytical solution for the decision boundary of the problem by equating

Where x is SV, y is ZV, $\mu_{1,k}$, $\mu_{2,k}$ are the means for kiki for the SV and ZC respectively, and $\beta_{2,k}$, the variances for SV and ZC, and $\mu_{2,k}$ are the priors. The variables with a subindex b refer to Bouba. We get

This is however difficult to solve analytically. However, the log-likelihoodis far better to get. A sample with SV=x and ZC=y would be classified as k whenever

That can be converted into

 $$$-\frac{1}{2}\left[(x-\mu_{1,k})^2 \wedge \frac{1,k}+(y-\mu_{2,k})^2 / \beta_{2,k} - (x-\mu_{1,b})^2 / \beta_{1,k} - (y-\mu_{2,k})^2 / \beta_{2,k} - (x-\mu_{1,b})^2 / \beta_{1,k} - (y-\mu_{2,k})^2 / \beta_{2,k} - (x-\mu_{1,b})^2 / \beta_{2,k} - (x-\mu_{$

```

We get better results at the cost of needing longer samples (at least 10s) and with more computing time (since computing the variance is more costly than computing the mean).
